ACKNOWLEDGEMENTS

I am sincerely indebted to my thesis advisor, Associate Professor Dr. Jiraporn Ungwitayatorn, for her kindness, helpful, valuable supervision, guidance and constructive criticism during my entire study.

My sincere and grateful appreciation are also expressed to Associate Professor Dr. Chanpen Wiwat, my co-advisor, for her guidance and correction in bioassay section.

I sincerely wish to thank Assistant Professor Dr. Weerasak Samee, Department of Pharmaceutical Chemistry and Pharmacognosy, Faculty of Pharmacy, Srinakharinwirot University, Nakornnayok for being a chairman of the defense committee.

Acknowledgement, Department of Pharmaceutical Chemistry, Faculty of Pharmacy, Mahidol University, for providing research facilities and supporting the important information. Natural Product Section, Research Division, National Cancer Institute for supporting the cytotoxicity activity test. As well, my special appreciation gives to my fellow graduate students at the Faculty of Pharmacy, Mahidol University, and other persons who have not been mentioned here for their help, friendship and encouragement.

Finally, I wish to express my gratitude and infinite thanks to my family for their love, concern, encouragement and precious spiritual support throughout my life.

SYNTHESIS, ANTI HIV-1 REVERSE TRANSCRIPTASE AND CYTOTOXIC ACTIVITY OF PHTHALIMIDE DERIVATIVES**SURATSAWADEE PIYAVIRIYAKUL 4636365 PYPP/M****M.Sc. (PHARMACEUTICAL CHEMISTRY AND PHYTOCHEMISTRY)****THESIS ADVISORS: JIRAPORN UNGWITAYATORN, Ph.D. CHANPEN WIWAT, Ph.D.****ABSTRACT**

The novel phthalimide derivatives were designed and synthesized by modifying of the phthalimide structures based on the three-dimensional quantitative structure-activity relationship (3D QSAR), comparative molecular field analysis (CoMFA) and comparative molecular similarity indices analysis (CoMSIA) studies. These derivatives were synthesized using phthalimide and substituted benzyl halide in the presence potassium hydroxide. Six newly synthesized compounds were evaluated for HIV-1 reverse transcriptase inhibitory activity by radioactivity assay at concentration 200 µg/mL using poly(rA).oligo(dT) as template-primer, methyl-³H]dTTP as substrate and doxorubicin (1.25 mM) as positive control. The synthesized compounds showed low inhibitory activity in the range of 7.9-22.9 % inhibition. Since infection with HIV-1 is associated with an increase risk of developing certain types of cancer, the previously and newly synthesized phthalimide derivatives have been subjected to cytotoxic activity testing using MTT colorimetric method against the cancer cell lines KB and HeLa and normal vero cell line. 1-Phthalimidomethyl-4-*tert*-butylbenzene, compound **36** demonstrated promising cytotoxic activity that was less toxic to normal cells.

CHAPTER I

INTRODUCTION

Acquired immunodeficiency syndrome (AIDS) is the most fatal disorder for which no complete successful chemotherapy has been developed so far (1). An asymptomatic period precedes AIDS in which the immune system becomes progressively compromised and unable to fight opportunistic infections and certain cancers (2). Human immunodeficiency virus subtype 1 (HIV-1), a retrovirus, has been found to be prevalent in causing this disease. The HIV pandemic poses one of the greatest challenges to global public health. In estimated 39.5 million people are living with HIV and approximately 4.3 million new infections in 2006 with 2.8 million (65%) of these occurring in sub-saharan africa and important increases in eastern europe and central asia (3). Infection with the HIV-1 is associated with an increased risk of developing certain cancer, particularly Kaposi's sarcoma, non-Hodgkin's lymphoma, Hodgkin's disease, cervical cancer and 20 other cancer types (4-7). Recent data report that HIV inhibitors are also potent antiangiogenic, antitumor of Kaposi sarcoma and MCF-7, decrease proliferation of human myelocytic leukemia cell (8-11).

HIV-1 reverse transcriptase (HIV-1 RT) has a vital role in the life cycle of the virus by catalyzing the transformation of the viral single-stranded RNA genome into a double-stranded DNA genome needed for viral genome integration. Two classes of HIV-1 RT inhibitors (HIV-1 RTIs) are used in clinical practice. The first HIV-1 RTIs identified are the nucleoside reverse transcriptase inhibitors (NRTIs), which constitute the backbone of the first line therapeutic intervention. After conversion to their triphosphates, which are the pharmacologically active species within cells, the nucleoside analogs mimic the natural substrates of the enzyme. However, since the analogs lack the 3'-OH group necessary for DNA chain elongation, they prematurely terminate the transformation of the viral RNA into DNA. Eight nucleoside HIV-1 RTIs, i.e., zidovudine (AZT), didanosine (ddI), zalcitabine (ddC), stavudine (d4T), lamivudine (3TC), abacavir (ABC), tenofovir (TDF) and emtricitabine (ETC) were

(fAPV), tipranavir (TPV) and darunavir (TMC114) were approved for treatment HIV infection (12, 16-19).

Conceptually, the use of agents to block viral entry is also an attractive modality in the treatment of HIV infection. HIV fusion inhibitor, enfuvirtide (T20), the peptidic compound that blocks fusion by directly binding to gp41 was recently licensed by the United States Food and Drug Administration (FDA) for treatment of HIV infected individuals, including those who failed to respond to prior antiretroviral therapy (12, 20-21).

The NNRTIs are our research group interest. The aim of this thesis is to synthesize more compounds in the phthalimide series with modifying structures based on the previous 3D QSAR studies, i.e., comparative molecular field analysis (CoMFA) and comparative molecular similarity indices analysis (CoMSIA) (22). Based on the steric contour map from CoMFA and hydrophobic contour map from CoMSIA, more new compounds in phthalimide series, were synthesized and evaluated for their HIV-1 RT inhibitory. Since several studies have reported that some HIV-1 RT inhibitors, e.g., AZT also exhibited antitumor activity (9,11), the synthesized phthalimide derivatives were subjected to cytotoxic activity test as well.

CHAPTER II

LITERATURE REVIEW

A. AIDS and molecular biology of HIV-1 virus

1. Acquired immunodeficiency syndrome (AIDS)

The human immunodeficiency virus (HIV), that causes acquired immunodeficiency syndromes (AIDS), was first identified 20 years ago. Similarly, there are currently two recognized strains of HIV, HIV-1 and HIV-2. HIV-1 is more virulent, more easily transmitted and is the cause of the majority of HIV infections globally, while HIV-2 is less easily transmitted and is largely confined to West Africa (1-3). According to the latest figures published in the UNAIDS/WHO 2006 AIDS epidemic update, an estimated 39.5 million people are living with HIV. There were 4.3 million new infections in 2006 with 2.8 million (65%) of these occurring in sub-Saharan Africa and important increases in Eastern Europe and Central Asia (3).

HIV primarily infects viral components of the immune system such as CD4⁺ T cell, macrophages and dendritic cell (23). It also directly and indirectly destroys CD4⁺ T cell. As CD4⁺ T cells are required for the proper functioning of the immune system, when enough CD4⁺ T cells have been destroyed by HIV, the immune system functions poorly, leading to AIDS. Many of the problems faced by people infected with HIV result from failure of the immune system to protect from opportunistic infections and cancers (24-25).

2. The viral genome

The genomic complexity and heterogeneity of HIV underlie its pathogenicity. The 9 kilobase single-stranded HIV RNA genome consists of ten open reading frames encoding structural genes, i.e., *gag*, *env*, *pol*, regulatory genes i.e., *tat*, *rev*, and accessory genes i.e., *nef*, *vif*, *vpr*, and *vpu* (Figure 1) (25). The structural genes are essential for retroviral replication, for instance, the *gag* gene encodes the precursor for virion capsid proteins and the *env* gene encodes the two major envelope glycoproteins,

gp120 and gp 41. These glycoproteins become embedded all over the host cell membrane and this membrane ultimately becomes the viral envelope as the virus "buds" out of cell as it completes its maturation process (25-26). The *pol* gene encodes the viral enzymes protease, reverse transcriptase, and integrase. These enzymes are produced as a *gag-pol* precursor polyprotein, which is processed by viral protease. The regulatory genes are required for control of the viral replication cycle. The *tat* gene acts as a potent transcriptional activator by binding to the transactivation response (TAR) element of the HIV long terminal repeat (LTR) to mediate viral gene expression. The *tat* gene produces proteins which turn on other HIV genes, greatly increasing the activity of the virus. Without *tat*, HIV is largely or totally inactive (26-28). The major role of *rev* is to regulate the expression of HIV proteins by controlling the export rate of mRNAs (28). The accessory genes products perform important functions related to virion maturation, release and infectivity. The *nef* interacts with host cell signal transduction proteins, down regulates expression of cell-surface proteins (CD4 and MHC Class I), and can induce apoptosis in non-infected cells. The *vif* promotes virion maturation and infectivity. The *vpr* is involved in targeting the nuclear localization of preintegration complexes, arrests infected cells at G2 phase of cell cycle, and inhibits cell division (28). The *vpu* acts in the degradation of CD4 in the endoplasmic reticulum and the enhancement of virion release from the plasma membrane (29).

Figure 1. The viral genome of HIV-1 (28).

3. HIV-1 virion

The mature HIV-1 virion is a roughly spherical particle with a diameter of approximately 100 nm. The schematic drawing of the HIV-1 virion is shown in Figure

2. The outer surface of the virus is enveloped by a lipid bilayer that is derived from the membrane of the host cell. The envelope is acquired during virion budding and is studded with approximately 72 spikes formed by the two major viral envelope glycoproteins, gp 120 and gp 41. The gp 120 are anchored to the virus via interactions with the transmembrane protein (gp 41). A shell of matrix (p 17) lines the inner surface of the viral membrane and a conical capsid core particle comprising of the capsid protein (p 24) is located in the center of the virus. The capsid particle encapsidates two copies of the unspliced viral genome, stabilized by nucleocapsid protein (p7) and also contains three essential viral enzymes: reverse transcriptase (p64), integrase (p32), and protease (p10) (2, 25, 28). Major histocompatibility complex (MHC) is protein complex on surface of cells. MHC presents antigens to CD4.

Figure 2. Schematic drawing of the HIV-1 virion (24).

4. The replication cycle of HIV-1

HIV infection begins with the interaction of the HIV glycoprotein (gp) 120 with the CD4 receptor on the surface of the target cell (Figure 3). Following CD4 binding, material change in the HIV gp 120/gp 41 complex is induced by interaction of gp 120 with the chemokine receptors CCR5 or CXCR4. This change in conformation exposes gp 41 and allowing it to initiate fusion of the membranes (24). After the fusion of membranes, the nucleocapsid enters the cytoplasm. The viral RNA, still enclosed in the viral capsid, is uncoated in a process aided by capsid proteins (p24) and cellular protein called cyclophilins (23-26). After uncoating process, reverse

transcription of the viral RNA generates a double-stranded DNA copy (cDNA) of the genome. The newly formed HIV DNA enters the host cell nucleus and integrates into the host cell genome via the action of the viral integrase leading to the formation of a provirus. The provirus may remain inactive for several years, producing few or no new copies of HIV. When the host cell receives a signal to become active, the provirus uses a host enzyme called RNA polymerase to create copies of the HIV genomic material, as well as shorter strands of RNA called messenger RNA (mRNA). The mRNA is used as a blueprint to make long chains of HIV proteins. The HIV life cycle final event is the maturation of cell-free particles upon action of HIV-1 protease (HIV-1 PR) (25). HIV-1 PR cleaves the polyproteins into functional enzymes and structural proteins. These matured viruses, if assembled correctly, are then capable of productive function when they encounter appropriate target cells and start the new replication cycles.

Figure 3. Schematic drawing of the HIV-1 replication cycle (25).

B. The development of anti HIV-1 agents

The current treatment for HIV/AIDS involves utilizing combination of a number of drugs. Although this therapy can suppress viral loads to below detectable levels, suppression has been observed to be reversible, especially once drug therapy is stopped (30-36). In addition, issues of patient adherence, drug toxicity, the emergence of multidrug-resistant phenotypes, and the presence of persistent reservoirs of virus

replication have highlighted the need to develop alternative therapeutic approaches utilizing other targets essential in the viral replication cycle.

Many steps in the HIV life cycle can be considered as a potential target for antiviral chemotherapy. The key in selective antiviral therapy is therefore to identify any process that is essential for the replication of the virus, but not for the survival of the cell. The gained knowledge about the replication cycle of the HIV virus has led to the extraction of virus-specific processes. Predominantly, scientists have focused their attentions on the following processes: 1) viral binding to target cells, 2) virus cell fusion, 3) virus uncoating, 4) reverse transcription of viral genomic RNA, 5) viral integration, 6) gene expression, and 7) protease activity. So far, the two strategies, 4 and 7 have been proven to be the most successful in the search for drugs that can be used for treatment of AIDS (29). These two targets will be described briefly in the following sections.

1. HIV-1 reverse transcriptase

Reverse transcriptase (RT) is essential for the life cycle of HIV. It converts the single stranded genomic RNA into the double stranded DNA version which is subsequently integrated into the host chromosome and passed on to all progeny cells (37-39). The HIV-1 RT molecule is a heterodimer consisting of a 560 residue chain (called p66) and a second chain comprising the initial 440 residues of p66 (called p51). Crystal structures of HIV RT reveal that the p66 subunit folds into five domains named finger, palm, thumb, connection, and RNaseH and that the p51 subunit comprises the first four domain of p66 (Figure 4). Whilst the equivalent domains from each subunit have a broadly similar fold, especially the finger and thumb domains, their relative arrangement in the two subunits is radically different. The p66/p51 HIV-1 RT heterodimer contains one DNA polymerization active site and one RNaseH active site, both of which residue in the p66 subunit at spatially distinct regions. Although the p51 subunit contains the same amino acid sequence that comprises the DNA polymerase domain of the p66 subunit, the polymerase active site in p51 is not functional (40).

Figure 4. Structure of the HIV-1 RT and the location of the NRTI and NNRTI binding sites (38).

Because of its pivotal role in the HIV life cycle, HIV RT is a primary target for antiretroviral agents. Two major classes of inhibitors that inhibit the polymerase activities of HIV-1 RT have been identified, nucleoside/nucleotide reverse transcriptase inhibitors (NRTIs), and non-nucleoside reverse transcriptase inhibitors (NNRTIs). NRTI binds at the polymerase active site. The polymerase active site, as defined by the three aspartic acid residues Asp 110, Asp 185 and Asp 186 resides in the palm subdomain (37-40). NRTI mimics normal substrates of HIV-1 RT but lack the 3'-OH group required for DNA chain elongation, which causes premature termination of the growing viral DNA strand (40). NNRTI binds to a hydrophobic pocket on HIV-1 RT ca. 10-15 Å from the NRTI site (polymerase active site) and is primarily consisted of Leu100, Lys101, Lys103, Val106, Thr107, Val108, Val179, Tyr181, Tyr188, Val189, Gly190, Phe227, Trp229, Leu234, and Tyr318 in p66 (38). The putative entrance of the pocket is proposed to be located at the interface of the p66/p51 heterodimer and is primarily formed by Pro95, Leu100, Lys101, Lys103, Val179, and Tyr181 of p66 (40-41). The side chains of several residues, especially

those of Tyr181 and Tyr188, assume significant conformational changes on the binding of NNRTIs. This binding event alters the conformation of active site residues hampering normal enzymatic activity (41).

2. HIV-1 protease

HIV-1 protease (HIV-1 PR) is a symmetrical homodimer enzyme. It belongs to the family of aspartic proteases, which have two aspartic acid residues at the active site. This was confirmed through pepstatin A inhibition, an aspartic protease selective inhibitor, and by site-directed mutagenesis of the active site Asp25, which led to abolition of the catalytic activity. Examples of the aspartic proteases are pepsin, cathepsin D, renin, chymosin, penicillopepsin, plasmepsins and *Rhizopus* pepsin. General feature of HIV-1 PR structure is illustrated in Figure 5. Its C_2 symmetric homodimeric structure is consisting of two identical 99-amino acid chains. The active site, with the two catalytic aspartate residues Asp25 and Asp25', is located at the interface between the two monomers. Two β -hairpin structures, called 'flaps', are positioned over the active site. They undergo structural changes on binding of the inhibitor molecule. In the unliganded protease structure, the conformation of the flaps is open, thereby exposing the active site, whereas in the ligand complex, the flaps form a roof over the active site and the ligand. The flaps cover to a large extent of the bound ligand. This arrangement is advantageous for the design of inhibitors, because it offers a large number of tight interactions between the enzyme and the inhibitor. The PR dimer forms a series of subsites, i.e., S_3 , S_2 , S_1 , S_1' , S_2' , and S_3' which correspond to the binding sites of P_3 , P_2 , P_1 , P_1' , P_2' , and P_3' residues of substrate, where the scissile bond is located between the P_1 and P_1' positions (Figure 5) (42-44).

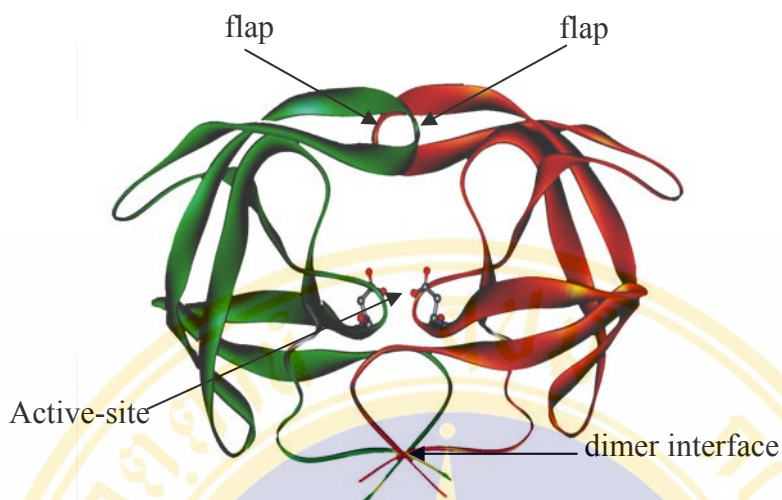

Figure 5. Structure of the HIV-1 PR binding site (42).

Figure 6. Standard nomenclature for substrate residues and their corresponding binding sites (43).

HIV-1 PR catalyzes the hydrolysis of specific peptide bonds within the HIV-1 *gag* and *gag-pol* polyproteins to generate the various structural and functional proteins essential for viral replication. It cleaves the p55 *gag* precursor into the four structural proteins, forming the core of the virion, p17, p24, p8 and p7. It also processes the p160 *gag/pol* precursor to liberate the structural elements just mentioned, and enzymes of the virus, i.e., the protease itself, the reverse transcriptase, and the endonuclease or integrase. The water molecule that binds between the enzyme (Ile50 and Ile50') and inhibitor is thought to position a peptide substrate, stretching the peptide bond out of

planarity toward a tetrahedral transition state which stabilized by a second water molecule (Figure 7) (44).

Figure 7. Hydrogen-bonding interactions between a cyclic peptidomimetic inhibitor and HIV-1 PR (44).

C. Antiretroviral agents

Currently, 20 antiretroviral drugs in 3 mechanistic classes were already approved for the treatment of HIV infection, i.e., HIV-1 RT inhibitors, HIV-1 PR inhibitors and HIV entry inhibitors (Table 1).

Table 1. Approved anti HIV-1 drugs.

Class	Generic name	Trade name	Company	Approval
NRTIs	Zidovudine (AZT)	Ritovir	GlaxoSmithkline	1987
	Didanosine (ddI)	Videx	Bristol Mayers Squibb	1991
	Zalcitabine (ddC)	Hivid	Hoffman-LaRoche	1992
	Stavudine (d4T)	Zerit	Bristol Mayers Squibb	1994
	Lamivudine (3TC)	Epivir	GlaxoSmithkline	1995
	Abacavir (ABC)	Ziagen	GlaxoSmithkline	1998
	Tenofovir (TDF)	Viread	Gilead Science	2001
	Emtricitabine (ETC)	Emtriva	Gilead Science	2003
NNRTIs	Nevirapine (NVP)	Viramune	Boeringer-Ingelheim	1996
	Delavirdine (DLV)	Rescriptor	Pharmacia & Upjohn	1997
	Efavirenz (EFV)	Sustiva	DuPont Merck	1998
PIs	Saquinavir (SQV)	Invirase	Hoffman-LaRoche	1995
	Ritonavir (RTV)	Norvir	Abbott Laboratories	1996
	Indinavir (IND)	Crixivan	Merck & Co.	1996
	Nelfinavir (NFV)	Viracept	Pfizer	1997
	Amprenavir (APV)	Agenerase	GlaxoSmithkline	1999
	Lopinavir/ritonavir	Kaletra	Abbott Laboratories	2000
	Atazanavir (ATZ)	Reyataz	Bristol Mayers Squibb	2003
	Fosamprenavir	Lexiva	GlaxoSmithKline	2003
	Tipranavir (TPV)	Aptivus	Boeringer-Ingelheim	2005
	Darunavir (TMC114)	Prezista	Tibotec, Inc.	2006
Fusion inhibitor	Enfuvirtide (T-20)	Fuzeon	Hoffman-LaRoche	2003

1. Nucleoside reverse transcriptase inhibitors (NRTIs)

NRTIs acting as alternative substrates or “false building blocks”, they compete with physiological nucleotides, differing from these only by a minor modification in the sugar (ribose) molecule. The incorporation of nucleosides aborts DNA synthesis, as phosphodiester bridges can no longer be built to stabilize the double strand. NRTIs are converted to the active metabolite only after endocytosis, whereby they are phosphorylated to the active triphosphate derivatives. NRTIs are important components of almost all AIDS combination regimens. Although they are potent inhibitors of HIV replication, and are rapidly absorbed when taken orally, they can cause a wide spectrum of side effects. The currently available NRTIs are zidovudine (AZT), didanosine (ddI), zalcitabine (ddC), stavudine (d4T), lamivudine (3TC), abacavir (ABC), tenofovir (TDF), and emtricitabine (ETC), structures as shown in Figure 8.

Figure 8. Structures of US FDA approved NRTIs.

3'-Azido-3'-deoxythymidine (AZT, Zidovudine, Retrovir[®]) was the first antiretroviral agent to be put on the market in 1987 (45). Early therapeutic interventions in asymptomatic individuals showed an initial clinical benefit but was not appear to be maintained for a prolonged period. The anti-HIV-1 activity of AZT stimulated the evaluation of a wide variety of nucleoside derivatives. AZT can cause severe side effect such as bone marrow suppression (46). AZT showed an IC₅₀ value of 0.002 μM in MT-4 cells infected at a multiplicity of infection (m.o.i.) of 0.01 (47).

2',3'-Dideoxyinosine (ddI, Didanosine, Videx[®]) is a nucleoside analogue that has been well investigated and showed good efficacy in numerous randomized studies (48). Didanosine was approved by the US FDA for the treatment of patients in whom AZT treatment had failed or who had become intolerant to AZT. The most serious side effect of didanosine is pancreatitis (49). Didanosine showed an *in vitro* IC₅₀ range from 2.5-10 μM in lymphoblastic cell lines and 0.01-0.1 μM in monocyte/macrophage cell cultures (50).

2',3'-Dideoxycytidine (ddC, zalcitabine, Hivid[®]) is an analogue of the nucleoside deoxycytidine. In 1993, ddC was approved for used in combination with AZT for HIV infection. The side effect of ddC is peripheral neuropathy whose symptoms involve tingling, burning, pain or numbness in the hands or feet (51). In laboratory and clinical isolates, ddC showed potent antiviral activity against HIV-1(IIIB) strain on ATH8 cell with IC₅₀ value of 30 μM (52).

2',3'-Didehydro-3'-deoxythymidine (d4T, stavudine, Zerit[®]) was the second thymidine analog introduced after AZT. Stavudine is one of the more effective nucleoside analogs currently in clinical use for HIV infection. Stavudine was approved by the US FDA for the treatment of patients who are intolerant to zidovudine or didanosine. Stavudine can cause the same side effect as ddC, i.e., peripheral neuropathy (53). Stavudine showed an IC₅₀ value of 19 μM in MT-4 cell infected with HIV-1(IIIB) strain (54).

2',3'-Dideoxy-3'-thiacytidine (3TC, lamivudine, Epivir[®]) has potent antiretroviral activity *in vitro* with good oral bioavailability, and less toxicity than AZT (55). Lamivudine is frequently used as a component in Combivir[®] (lamivudine and zidovudine) and Trizivir[®] (abacavir, zidovudine and lamivudine). Its main disadvantage is rapid development of resistance, and a single point mutation (M184V)

is sufficient for loss of effectiveness. The major reported side effects of lamivudine are pancreatitis and peripheral neuropathy (56-57). Lamivudine showed an *in vitro* IC₅₀ value of 0.4 μM in MT-4 cells infected at a m.o.i. of 0.01 (57).

Abacavir (ABC, Ziagen[®]) is a potent and mostly well-tolerated nucleoside with good CNS penetration due to its capable of crossing the blood-brain barrier. It has been well tolerated but the main side effect being hypersensitivity reactions, which sometimes can be dangerous. Strains that are resistant to AZT or lamivudine are generally sensitive to abacavir, whereas strains that are resistant to AZT and lamivudine are not sensitive to abacavir. Abacavir is given orally and has a high bioavailability of 83%. It is metabolized primarily through alcohol dehydrogenase or gluconyl transferase (58-60). When tested with normal human peripheral blood lymphocytes against fresh clinical isolates of HIV-1 obtained from antiretroviral drug-naive patients, the mean 50% inhibitory concentration (IC₅₀) was 0.26 μM (0.07 μg/ml); the corresponding IC₅₀ of zidovudine (ZDV), didanosine (ddI), and zalcitabine (ddC) were 0.23, 0.49, and 0.03 μM, respectively (60).

Tenofovir (Viread[®]) acts as a false building block similarly to nucleoside analogues, targeting the enzyme reverse transcriptase. However, in addition to the pentose and nucleic base it is monophosphorylated, and is therefore referred to as a nucleotide. The more accurate description of the substance is tenofovir disoproxil fumarate which is a prodrug of tenofovir (61). Tenofovir showed an *in vitro* IC₅₀ value of 29 μM in PBMC cell infected with HIV-1(IIIB) strain (62).

Emtricitabine (ETC, Emtriva[®]) is a synthetic nucleoside analogue of cytosine. It is the (-)-enantiomer of a thio analogue of cytidine and it differs from other cytidine analogs by a fluorine in the 5 position. Emtricitabine, in combination with other antiretroviral agents, was approved for the treatment of HIV infection in adults age 18 and older. Emtricitabine can cause some side effects, including nausea, vomiting, abdominal pain, lack of appetite, weight loss, difficulty breathing, and fatigue (63-65). Emtricitabine showed an *in vitro* IC₅₀ more than 100 μM in PBMC cell infected with HIV-1(LAV) strain (65).

series have demonstrated that the diazepinone N-11 position needs an alkyl group e.g. ethyl or cyclopropyl group and 7-position of the pyridobenzodiazepinones or 4-position of the dipyridodiazepinones requires a lipophilic group such as methyl group (41). In rare cases, it may cause serious hepatic toxicity. Nevirapine was approved by US FDA in 1996. Nevirapine showed IC_{50} value of 0.04 μ M in MT-4 cells infected at a m.o.i. of 0.01 (70-71).

Delavirdine (Rescriptor[®], U-90152S), the bisheteroaryl piperazine derivative, was the second NNRTI approved by US FDA. The development of delavirdine was based on the modification of the original molecule N-ethyl-2-[4-[4-methoxy-3,5-dimethylphenylmethyl]-1-piperazinyl]-3-pyridinamine (U-80493E). Replacement of the methylene linkage by carbonyl group and phenyl ring by indole ring greatly enhanced the HIV-1 RT inhibitory activity. Delavirdine with two aromatic groups, i.e., 5-methanesulfonamidoindole and 3-isopropylaminopyridine linking with carbonylpiperazine exhibited an IC_{50} of 0.26 μ M against HIV-1 RT (wild-type) (72-73). Delavirdine exhibited good absolute bioavailability in preclinical studies and serum drug levels in excess of those needed for in vitro antiviral activity was safely maintained for prolonged periods of time. Delavirdine prevented the spread of HIV-1 in human lymphocytes significantly longer than AZT at the same concentration. Although delavirdine was less effective against the known non-nucleoside-resistant forms of HIV-1 RT (Tyr181Cys and Lys103Asp) as compared to wild-type RT, it still demonstrated significant activity against these mutant RTs in vitro (IC_{50} 8 μ M). Due to requiring three times daily dosing, delavirdine is currently rarely prescribed, although it is likely to be approximately as effective as nevirapine and efavirenz (15).

Efavirenz (Sustiva[®], Stocrin[®]) was the third NNRTI approved and the first in which it was demonstrated that NNRTIs were at least as effective as protease inhibitors. Efavirenz is a benzoxazinone derivative, consisting of chlorine atom at position 6, trifluoromethyl and cyclopropylethynyl at position 4 of benzoxazinone ring system. Efavirenz has shown good antiviral potency, high oral bioavailability, and favorable profile against a number of mutant RTs. The most common side effects of efavirenz are rash, nausea, dizziness, diarrhea, headache and insomnia and it is contraindicated in pregnancy (74). Lipids are not as favorably affected as with nevirapine, and hepatotoxicity is less frequent. Efavirenz showed IC_{50} value of 80 μ M

in MT-4 cell infected with HIV-1 (IIIB) strain and this was the lowest concentration that exhibited signs of cytotoxicity (74-77)

3. HIV-1 protease inhibitors

HIV-1 PIs are compounds which bind to the active site of HIV-1 PR and prevent the processing of viral polyprotein precursors (*gag* and *gag-pol*). This results in the production of immature, non-infectious viral particles, thus inhibiting the replication and proliferation of HIV (43). PIs are almost always used in combination with at least two other anti-HIV drugs. Anti-HIV drug combinations, sometimes called cocktails, can reduce the amount of HIV in the patients's body (78). Several PIs are in clinical trials and eight of them (structures as shown in Figure 10) have been approved for using in AIDS patients.

Saquinavir (Ro 31-8959, Invirase[®], Fortovase[®]), from Hoffmann-La Roche was developed by substrate analogy, with replacement of the scissile dipeptide fragment of the natural substrate with a Phe-Pro hydroxyethylamine transition state insert (79). The basic design criterion relied on the observation that HIV-1 PR cleaves the sequences containing dipeptides Tyr-Pro or Phe-Pro. Mammalian proteases do not cleave peptide bonds followed by a proline; thus, this target promised selectivity. Because reduced amides and hydroxyethylamine isosteres most readily accommodate the amino acid moiety, they were chosen for further studies. Replacement of a proline at the P1' subsite by (S,S,S)-decahydroisoquinoline-3-carbonyl (DIQ) significantly improved the potency of the inhibitors (80). This general approach has previously been used with success by a number of researchers seeking to develop inhibitors of human renin. Following traditional SAR optimization, saquinavir emerged and became the first approved HIV-1 PI in December 1995. Saquinavir inhibits HIV-1 PR with a K_i value of 0.12 nM and shows specificity for that enzyme, with little inhibition of mammalian aspartyl proteases ($IC_{50} > 10$ mM) (81).

The first available formulation, Invirase[®], was a hard gel capsule and provided dismal bioavailability of about 4% due to poor absorption and extensive first pass clearance. Fortovase[®] is a new version of saquinavir and is better absorbed by the body, it has a stronger anti-HIV effect than Invirase[®]. The anti-HIV effect of Fortovase[®] seems to be similar to other available PIs (79-83).

Figure 10. Structures of clinically approved anti HIV-1 PR drugs.

Ritonavir (ABT-538, Norvir[®]) was the symmetry of HIV-1 PR, and the first symmetric inhibitor (A-77003) from Abbott (84). Researchers at Abbott initially sought to exploit the C₂ symmetry of HIV-1 PR by incorporating C₂ symmetry as an inhibitor design element. After extensive SAR investigation, which also involved partial desymmetrization, ritonavir emerged. The compound showed an IC₅₀ value against HIV-1 PR of 25 nM, with property of both an inducer and potent inhibitor of cytochrome P450 3A4. The latter property has been used to advantage for increasing the half-life of coadministered drugs (85-86). Ritonavir achieved FDA approval as Norvir[®] in February 1996.

Indinavir (MK-639, L-735,524, Crixivan[®]) was developed by Merck based on a transition-state mimetic concept (87), which had identified potent renin inhibitors based upon the PheΨ[CHOHCH₂]Phe transition state insert. In order to improve solubility and bioavailability, the P1/P2 portion of L-685,434 was replaced, first by the Roche P1'/P2' decahydroisoquinoline *tert*-butylamide (saquinavir) to generate L-704,486 (Figure 11), and subsequently by the pyridyl methylpiperazine moiety. Indinavir showed a K_i value against HIV-1 PR of 0.34 nM and is effective in antiviral cell culture with IC₅₀ values of 25-100 nM. It is synergistic with both nucleoside and nonnucleoside RTIs, and is unique among currently approved PIs in having a low degree of protein binding in human plasma (88-89). Indinavir therapy has been associated with kidney stones and urinary tract sludging, leading to the recommendation of increased fluid intake during its use. Indinavir was approved by FDA in March 1996 under the trade name Crixivan[®]

Figure 11. Design concept of indinavir (87).

Nelfinavir (AG-1343, Viracept[®]) was the first non-peptidomimetic PI, arose through a collaborative effort at Agouron and Lilly from a fusion of small peptidomimetic compounds with the Roche decahydroisoquinoline system. A key discovery during this evolution was the N-terminal 3-hydroxy-2-methylbenzoyl fragment, which subsequently found utility in other PIs (90). Nelfinavir showed a K_i value of 2 nM against HIV-1 PR with more than 78% bioavailability. Nelfinavir was launched in the US in March 1997 under the trade name Viracept[®] and was the first PI to be indicated for pediatric AIDS (91).

Amprenavir (VX-478, 141W94, Agenerase[®]) arose at Vertex from a structure-based design approach, which incorporated molecular weight minimization as a key goal. Its central core is identical to that of saquinavir, although both ends are quite different. The P2 group consists of tetrahydrofuran carbamate, whereas the P1'-P2' moieties consist of an isobutylphenyl sulfonamide with an added amide. This design gives amprenavir fewer chiral centers than saquinavir, facilitating synthesis and increasing water solubility to allow oral bioavailability as high as 40%-70%.

Amprenavir inhibited HIV-1 PR with a K_i value of 0.6 nM (92). In humans, its pharmacokinetic properties, such as more than 70% bioavailability and long half-life (10 hours) are consistent with twice-daily dosing. Amprenavir was FDA approved as Agenerase[®] in April 1999. Amprenavir in a combination with lamivudine and saquinavir was more potent than lamivudine or saquinavir alone, although less effective than indinavir (92-94).

Lopinavir is a second generation inhibitor from Abbott Laboratories, designed to preserve activity against Val 82 mutant virus arising with ritonavir therapy. The compound is based upon the same core insert as ritonavir but includes highly modified peripheral functionality (95). In particular, the P3 functionality interacts only minimally with Val 82, decreasing the sensitivity of the inhibitor to this particular mutation. Lopinavir showed a K_i value of 1.3 pM against HIV-1 PR and an antiviral IC_{50} value in cell culture of 6-17 nM. Administered alone, lopinavir is rapidly cleared from circulation (96-99). For this reason, the approved product Kaletra[®] is a formulation of lopinavir containing ritonavir, which blocks the metabolic degradation mediated by cytochrome P450 3A4 (CYP3A4) (98). Lopinavir/Ritonavir (Lopinavir/r, Kaletra[®]), which contains both lopinavir and ritonavir, has been approved in both capsule and liquid formulations for adults and children greater than 6 months of age with HIV. Ritonavir may increase concentrations of lopinavir by more than 100-fold. This results in blood levels of lopinavir that enhance its effectiveness against HIV (96). The new drug is used in combination with other anti-HIV drugs. Dyslipidemia appears to be a significant problem with lopinavir therapy. Kaletra[®] was approved in September 2000 (99).

Atazanavir (Reyataz[®]) is a once-daily PI that received approval by US FDA in June 2003 (100). Structure-activity studies with a series of azadipeptides designed to mimic the transition state of the peptide-cleavage reaction catalyzed by HIV-1 PR identified lead compounds that had either potent antiviral activity against mutant HIV-1 strains or good oral bioavailability, but not both. Lead optimization using X-ray structural data from an inhibitor-protease complex led to the discovery of atazanavir sulphate, which showed excellent antiviral activity with high oral bioavailability and could be used in combination with other antiretroviral agents (101). Atazanavir differs from the peptidomimetic PIs (e.g. saquinavir, nelfinavir) by its C₂ symmetric drug

interaction concerns, chemical structure and was designed and synthesized based on X-ray studies of an enzyme-dysazadipeptide complex (101-102). Atazanavir has an EC_{50} of 35 nmol/L against a variety of HIV-1 isolates in different cell types and is a highly selective and effective inhibitor of the HIV-1 PR *in vitro* (K_i , <1 nmol/L) (103).

Fosamprenavir (Lexiva[®], Telzir[®]), is an essentially inactive, highly water-soluble phosphate ester prodrug of amprenavir. It was synthesized to enhance oral bioavailability and solubility of amprenavir, thus allowing a reduction in the pill burden and offering the potential for improved patient compliance (104-106). Fosamprenavir calcium is a single stereoisomer with the (3*S*)(1*S*,2*R*) configuration. Fosamprenavir is rapidly and almost completely hydrolyzed to amprenavir and inorganic phosphate by cellular phosphatases in the gastrointestinal epithelium as it is absorbed (107). Fosamprenavir demonstrated efficacy when used as a sole PI administered twice-daily or in combination with ritonavir-boosting as a once-daily regimen in treatment-naïve patients. Fosamprenavir appears to have an adverse effect profile similar to that of other PIs (104). The most common adverse events reported were diarrhea, nausea, vomiting, fatigue, headache, abdominal pain, and rash. Co-administration of food with fosamprenavir tablets appears to have little effect on amprenavir absorption. As a result, fosamprenavir may be taken with or without food (105). Fosamprenavir was approved by the FDA on October 20, 2003, for the treatment of HIV infection in adults in combination with other antiretroviral agents (108).

Tipranavir (TPV, PUN-140690, Aptivus[®]), is a new class of non-peptidic PIs with activity against both wild-type virus and variants resistant to current PIs and is also characterized by a high genetic barrier (109). Tipranavir, a sulfonamide compound containing 5,6-dihydro-4-hydroxy-2-pyrone, was developed from 5-cyano-2-pyridyl sulfonamide derivative, PNU-109112, that exhibited a $K_i = 7$ pM against recombinant HIV-1 PIs and IC_{50} of 40 μ M in HIV-1 IIIB-infected H9 cell (110). Unfortunately, PNU-109112 was found to be converted both in cell culture *in vitro*, and in animal testing to a product with K_i about four orders of magnitude higher. Tipranavir was subsequently shown to suffer from excessive metabolic clearance, a fate which was later traced to an unusual enzymatic cleavage of the sulfonamide moiety (107). The simple replacement of the cyano group in the pyridyl ring of PNU-

109112 with a trifluoromethyl group conferred metabolic stability and high potency in the product. Tipranavir was resistant to sulfonamide cleavage, and the isomer with 3 α R,6R stereochemistry exhibited a $K_i = 8$ pM against recombinant HIV-1 PR (it also inhibited the HIV-2 PR with $K_i < 2$ nM). Tipranavir was highly specific for the viral enzyme; K_i values were in the μ M range for the human aspartyl pretease, cathepsins D and E, and pepsin. In HIV-1 IIIB-infected H9 cell, tipranavir showed antiviral activity with $IC_{50} = 30$ μ M, and $IC_{90} = 100$ μ M (110-112). It was also effective against ten AZT-resistant HIV-1 clinical isolates in primary PMBC, exhibiting a mean IC_{90} value of 0.15 μ M (109). In vitro assays, tipranavir was effective against strains of HIV that are highly resistant to indinavir, ritonavir, nelfinavir and saquinavir (111). Tipranavir was approved on June, 2005.

Darunavir (TMC114, UPI-94017, Prezista[®]), a newly class of peptidomic PIs from Tibotec, Inc. Prezista[®] in the form of darunavir ethanolate, was developed from structural analogues of amprenavir (19).

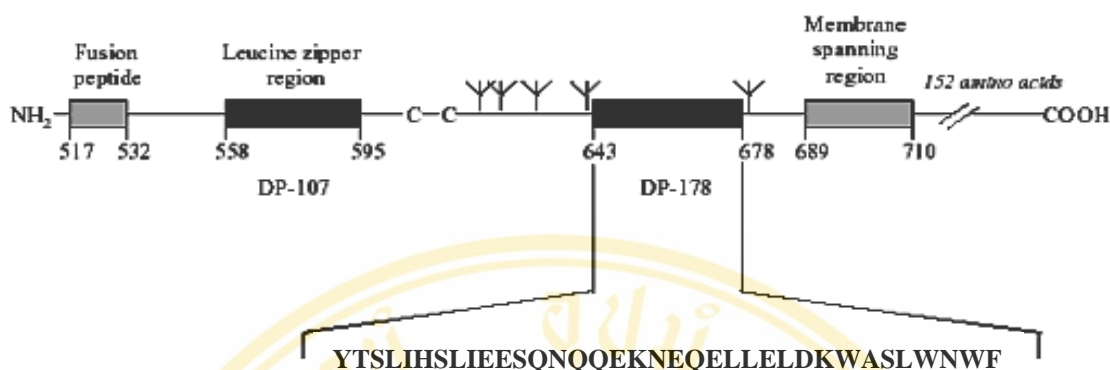

Darunavir showed inhibitory activity against wild-type HIV-1 and HIV-2. In vitro antiviral activity of darunavir against laboratory HIV-1 strains was evaluated in

acutely infected MT-4 cell, in PBMCs and in M/Ms. The EC_{50} of darunavir against different HIV-1 laboratory strains ranged from 1 to 5 nM and the corresponding EC_{90} ranged from 2.7 to 12 nM (113). Moreover, darunavir inhibited replication of HIV-2 with a EC_{50} of 4.2 nM and the EC_{90} of 13 nM, which was comparable with the activity observed against HIV-1 (113). The CC_{50} of darunavir was found to be $> 100 \mu\text{M}$, from which the selective index (CC_{50}/EC_{50}) was calculated to be $> 20,000$ for wild-type HIV (113-115). Darunavir was also potent against multi-PIs-resistant clinical HIV-1 variants isolated from patients who had not response to existing antiviral regimens after having received a variety of antiviral agents (116-118). Darunavir was approved by the FDA on June, 2006.

4. Fusion inhibitors

Enfuvirtide (T-20, DP-178, Pentafuside[®]), the first in a new class of anti HIV-1 drugs that inhibit the entry of the virus into cells, was approved by the US FDA in March 2003 for treatment of HIV-1 infection in treatment-experienced patients. Enfuvirtide is a synthetic 36 amino acids peptide (Figure 12) corresponding to residues 127-162 of the extracellular portion (ectodomain) of gp41 (or residues 643-678 in the gp160 precursor) of the HIV envelope glycoprotein. The molecular formula of enfuvirtide is $C_{204}H_{301}N_{51}O_{64}$, and its molecular weight is 4492 Da. (20). Considering its large size, the manufacture of enfuvirtide is very complex, currently involving 106 steps in the chemical pathway to give a powder for subcutaneous injection (119). Because of the large size of the molecule and the complexity of the manufacturing process, enfuvirtide is expensive even by antiretroviral standards (119). Although enfuvirtide is the most expensive antiretroviral to date, the cost effectiveness of enfuvirtide has been explored and been demonstrated to be within currently acceptable thresholds for both the US and UK (120). Enfuvirtide was approved for using with other anti-HIV drugs in the treatment of HIV infection and was approved for using in HIV infected adults and children 6 years of age or older whose HIV infection has not been controlled by other anti-HIV drugs.

(CH₃CO-Tyr-Thr-Ser-Leu-Ile-His-Ser-Leu-Ile-Glu-Glu-Ser-Gln-Asn-Gln-Gln-Glu-Lys-Asn-Glu-Gln-Glu-Leu-Leu-Glu-Leu-Asp-Lys-Trp-Ala-Ser-Leu-Trp-Asn-Trp-Phe-NH₂).

Figure 12. Structure of enfuvirtide (20, 119).

D. HIV-1 reverse transcriptase inhibitory activity test

The radioactive assay was developed for detection of the inhibitory activity of enzyme reverse transcriptase in virions, using polyadenylic acid [poly(rA)] as the template, oligodeoxythymidylic acid [oligo(dT)] as the primer, and radiolabeled thymidine 5'-triphosphate (TTP) as the substrate. HIV-1 RT used in the assay was obtained from an *Escherichia coli* expression system using a genetically engineered plasmid; the enzyme was purified to near homogeneity. The purified recombinant enzyme was sufficiently similar to the viral enzyme that it can be substituted for the latter in drug screening assay (122-123). Reverse transcription process is also specifically dependent on a divalent cation either Mg²⁺ or Mn²⁺, but the majority of the retroviruses preferentially use Mn²⁺. The optimal monovalent cation such as KCl is also required for this enzyme. The RTs of retroviruses generally require an optimum pH between 7 and 8 but the major activity is occurred at pH 8.0. Therefore, tris-HCl at pH 8.0 was chosen as the buffer for the assay. In addition, a sulfhydryl-containing compound such as dithiothreitol (DDT) was also used conventionally in RT assay as a reducing agent.

Compounds which bind selectively to the activity site of the enzyme should yield useful response. Unfortunately, such agents are not frequently encountered.

Compounds that bind to proteins in a relatively nonspecific fashion such as polyphenolic compounds are observed to have more generalized effects on a variety of enzyme system. In this case, the inclusion of bovine serum albumin (BSA) as a protective agent in an enzyme assay is optimal.

The general procedure consists of three main steps as follow:

1. Reverse transcriptase reaction

Recombinant HIV-1 RT, template-primer (rA)_n-P(dT)₁₂₋₁₈, substrate (methyl-³H)dTTP), sample and other reagents were incubate at 37°C for 60 minutes.

2. Stop reaction

The reaction was stopped by boiling the reaction mixture for 10 minutes. Eighty µL of each reaction mixture was applied to Whatman® grade DEAE cellulose paper and dried for 2 hours. The membrane was washed batchwise with (4x7 mL) 3% disodium hydrogenphosphate (Na₂HPO₄) for 5 minutes, followed by 2x7 mL of water for 2 minutes and 2 mL of absolute ethanol for 1 minute. The membrane was dried on the Petri-dish not less than 1 hour.

3. Detection of DNA

The dried membrane was transferred into a vial containing the scintillation cocktail (Ultima Gold, Packard), and radioactivity was measured by liquid scintillation system (TRI-CARB 2100RT, Packard).

The HIV-1 RT inhibition was the inhibition of the incorporation of [³H]-labeled substrate (dTTP) into a polymer fraction in the presence of a synthetic compound. The positive control of the assay was performed in the same manner to the preparation for the synthetic compounds, but an equivalent volume of solvent (DMSO) was added instead. The negative control was performed without the enzyme (124).

E. AIDS and cancer

An asymptomatic period precedes AIDS in which the immune system becomes progressively compromised and unable to fight opportunistic infections and certain cancers (2). AIDS related cancer, that many types of cancer are relatively frequent outcome of HIV. AIDS-associated cancers have focused on the interplay of immunity and viral infections and has increased of cancer pathogenesis. These cancers are sometimes called “AIDS malignancies”. There are many research to stimulate and

to increase knowledge of the underlying pathophysiology of HIV/AIDS-associated malignancies and the development of more effective interventions. There are three major of AIDS malignancies i.e., Kaposi's sarcoma (KS), Cervical cancer and Non-Hodgkin's lymphoma (NHL).

Kaposi's sarcoma (KS) is associated with human herpesvirus 8 (HHV-8). This virus is sometimes called "Kaposi's sarcoma-associated herpesvirus." The virus is likely transmitted through saliva. Fortunately, the number of case of KS has decreased dramatically since the introduction of potent anti-HIV therapy (5, 10, 125).

Cervical cancer is caused by certain types of human papillomavirus (HPV). This virus also can cause genital and oral warts. It is spread by contact with infected areas of the body. Some forms of this virus are low-risk for cancer (like HPV-6 and HPV-11) while other forms are high-risk for cancer (HPV-16 and HPV-18). Woman get regular Pap tests to detect any cell abnormalities (dysplasia) that may be caused by this virus and may indicate the beginnings of cancer. This same virus causes anal cancer. Some HIV-treating physicians are using the Pap test to screen for anal cancer in men and women. Successful anti-HIV therapy helps reduce, but does not eliminate, the risk of cervical cancer in women (5-6,125).

Non-Hodgkin's lymphoma (NHL) is associated with Epstein-Barr virus (EBV), a type of herpes virus that infected almost all humans by young adulthood. Lymphoma involves immune cell "B lymphocytes". Since these cell are almost everywhere in the body, tumors can arise in a number of locations (bone, brain, abdomen, lung, etc.) and spread through the body's lymphatic system (5-6, 125).

The national cancer of USA is stimulated to perform the research and increase the knowledges of HIV/AIDS-associated malignancies and the development of more effective interventions (125). The development of cancer is a multistep process through which cells gradually undergo a progressive series of alterations, which include mutation and selection for cells with increasing capacity for proliferation, survival, invasion and metastasis (126). The cytotoxic assay activity is the first biological screening for proliferation of cancer and there are many assays for testing for example, sulforhodamine B (SRB) assay, CellTiter Blue (CTB) cell viability assay, lactate dehydrogenase (LDH) cytotoxic assay, 3-(4,5-dimethylthiazol-2-yl)-2, 5-diphenyltetrazolium bromide (MTT) assay (127-130). Currently, several cytotoxic

screening assays are commonly used including MTT assay, CTB assay, LDH assay and SRB assay. The MTT assay has higher sensitivity for detecting cytotoxic effects (127).

F. The cytotoxic activity testing

The MTT assay is commonly applied as a preliminary screen to quantify cell proliferation, viability, sensitivity, and cytotoxicity (131-134). The MTT assay is based on the ability of a mitochondrial dehydrogenase enzyme from viable cells to cleave the tetrazolium rings of the pale yellow MTT and form a dark blue formazan crystals which is largely impermeable to cell membranes, thus resulting in its accumulation within healthy cells. Solubilization of the cells by the addition of a detergent results in the liberation of the crystals which are solubilized. The number of surviving cells is directly proportional to the level of the formazan product created (135-137). The color can then be quantified using a simple colorimetric assay. The results can be read on a multiwell scanning spectrophotometer (ELISA reader).

CHAPTER III

CHEMICAL EXPERIMENTAL

A. Equipment and chemicals

1. Equipment

Analytical balance model 2842	Sartorius, USA
Chromato-VUE cabinet (Model CC-60)	UVP Inc., USA
Elemental analyzer (PE 2400 series II)	Perkin Elmer, Germany
FTIR (FTIR 550)	Nicolet, USA
¹ H NMR (DPX-3000) spectrophotometer	Bruker, Switzerland
Magnetic stirrer (MR 3001K)	Heidolph, Germany
Mass spectrometer (MAT 90)	Finnigan, Germany
Melting point apparatus (model 9100)	Electrothermal, UK
Rotary evaporator	Eyela, Japan

2. Chemicals

Acetone	J.T. Baker
3-(Bromomethyl) benzonitrile	Fluka, Switzerland
Chloroform	Lab Scan
Dichloromethane	Lab Scan
Ethyl acetate	J.T. Baker
Hexane	J.T. Baker
Methanol	Lab Scan
3-Methoxybenzyl chloride	Fluka, Switzerland
2-Methylbenzyl bromide	Fluka, Switzerland
4-Methylbenzyl chloride	Fluka, Switzerland
3-Nitrobenzyl chloride	Fluka, Switzerland
Phthalimide	Fluka, Switzerland
Potassium hydroxide	Merck, Germany

Pyridine	J.T. Baker
Sodium sulfate	Merck, Germany
Silica gel 60 No. 1.07734	Merck, Germany
Silica gel F ₂₅₄ (0.2 mm)	Merck, Germany
Sea sand	Fluka, Switzerland

B. Methods

All new compounds were characterized by spectroscopic methods, i.e., infrared (IR) spectroscopy, proton nuclear magnetic resonance (¹H NMR) spectroscopy, mass spectrometry (MS) and elemental analysis. IR spectra were recorded on FTIR Nicolet 550, using the potassium bromide pellet technique. ¹H NMR spectra were obtained on an ADVANCE 300 MHz Digital NMR Spectrophotometer (Bruker Switzerland DPX-3000). Chemical shifts were reported in ppm related to the internal standard, tetramethylsilane (TMS). The NMR solvent used was deuterated chloroform (CDCl₃ δ_H = 7.2 ppm). Mass spectra were determined on a MAT 90 (Finnigan) mass spectrometry using EI method. Percentage of carbon, hydrogen and nitrogen were obtained from a CHNS/O analyzer (Perkin Elmer PE2400 series II) and the results were within 0.4 % of theoretical values. Melting point of all products were determined on an Electrothermal model 9100 capillary melting point apparatus. The crude products were purified by column chromatography using silica gel, E. Merck (70-230 mesh) and recrystallization. Thin layer chromatography (TLC) was carried out on silica gel GF₂₅₄ coated aluminum sheets 20 x 20 cm (E. Merck) with spots visualized by UV light (254 nm). All solvents were reagent grade and when necessary, were purified and dried by standard methods.

1. 1-Phthalimidomethyl-2-methylbenzene

To a solution of phthalimide (2 g, 13.6 mmol) in *N,N*-dimethylformamide (40 mL) was added 2-methylbenzyl bromide (4 mL, 29.4 mmol) and potassium hydroxide solution (0.31 g, 5.5 mmol) 10 ml. The reaction mixture was refluxed for 6 hours at 190°C. The mixture was extracted with chloroform (30 mL) and water (3x15 mL). The organic phase was dried over anhydrous sodium sulfate, filtered and concentrated in vacuo. The residue was purified by column chromatography (silica gel 60 No. 1.07734) using hexane/ethyl acetate (4:1) as eluent. Recrystallization from chloroform/methanol gave compound **34** (1.50 g, 44.70% yield) as a white needle crystal; mp 158-159°C. IR (KBr) (cm^{-1}): 3466 (overtone C=O), 3087 (aromatic C-H), 2920 (aliphatic C-H), 1705 (C=O), 1424 (C=C), 1319 (C-N); ^1H NMR (CDCl_3): δ 2.46 (s, 3H, CH_3), 4.85 (s, 2H, $\text{CH}_2\text{-N}$), 7.09-7.15 (m, 3H, benzene H3, H5, H6), 7.21-7.25 (m, 1H, benzene H4), 7.67-7.73 (m, 2H, phthalimide H3', H4'), 7.84 (dd, $J = 3.0, 5.4$ Hz, 2H, phthalimide H2', H5'); MS: m/z (relative intensity): M^+ 251 (100), 236 (19.73), 160 (23.88), 130 (10.43), 104 (53.36), 78 (14.35), Anal. Calcd. for $\text{C}_{16}\text{H}_{13}\text{NO}_2$ (251.28): C, 76.48; H, 5.21; N, 5.57. Found: C, 76.92; H, 5.54; N, 5.43. TLC (ethyl acetate/hexane [1:1]): R_f of phthalimide = 0.471, R_f of 2-methyl benzyl bromide = 0.824, and R_f of compound **34** = 0.612.

2. 1-Phthalimidomethyl-4-methylbenzene

To a solution of phthalimide (0.5 g, 3.40 mmol) in N,N-dimethylformamide (40 mL) was added 4-methylbenzyl bromide (1.0 mL, 7.54 mmol) and potassium hydroxide solution (0.13 g, 2.32 mmol) 10 mL. The reaction mixture was refluxed for 6 hours at 190°C. The mixture was extracted with chloroform (30 mL) and water (3x15 mL). The organic phase was dried over anhydrous sodium sulfate, filtered and concentrated in vacuo. The residue was purified by column chromatography (silica gel 60 No. 1.07734) using hexane/ethyl acetate (2:1) as eluent. Recrystallization from chloroform/methanol gave compound **35** (0.41 g, 43.04% yield) as a white needle crystal; mp 117-118°C. IR (KBr) (cm⁻¹): 3459 (overtone C=O), 3065 (aromatic C-H), 2940 (aliphatic C-H), 1726 (C=O), 1438 (C=C), 1319 (C-N); ¹H NMR (CDCl₃): δ 2.28 (s, 3H, CH₃), 4.78 (s, 2H, CH₂-N), 7.10 (d, *J* = 7.8 Hz, 2H, benzene H₃, H₅), 7.31 (d, *J* = 8.1 Hz, 2H, benzene H₂, H₆), 7.64-7.70 (m, 2H, phthalimide H_{3'}, H_{4'}), 7.81 (m, *J* = 3.0, 5.4 Hz, 2H, phthalimide H_{2'}, H_{5'}); MS: *m/z* (relative intensity): M⁺251 (100), 236 (60.36), 208 (13.01), 160 (20.34), 130 (26.97), 105 (13.96), 104 (27.04), 77 (15.58). Anal. Calcd. for C₁₆H₁₃NO₂ (251.28): C, 76.48; H, 5.21; N, 5.57. Found: C, 76.93; H, 5.45; N, 5.42. TLC (ethyl acetate/hexane [1:2]): R_f of phthalimide = 0.383, R_f of 4-methylbenzyl bromide = 0.617, and R_f of compound **35** = 0.468.

3. 1-Phthalimidomethyl-4-*tert*-butylbenzene

To a solution of phthalimide (1 g, 6.79 mmol) in N,N-dimethylformamide (40 mL) was added 4-*tert*-butyl benzyl bromide (2.4 mL, 13.2 mmol) and potassium hydroxide solution (0.16 g, 2.85 mmol) 10 mL. The reaction mixture was refluxed for 8 hours at 190°C. The mixture was extracted with chloroform (30 mL) and water (3x15 mL). The organic phase was dried over anhydrous sodium sulfate, filtered and concentrated in vacuo. The residue was purified by column chromatography (silica gel 60 No. 1.07734) using hexane/ethyl acetate (4:1) as eluent. Recrystallization from chloroform/methanol gave compound **36** (0.63 g, 31.66% yield) as a white solid crystal; mp 93-94°C. IR (KBr) (cm⁻¹): 3495 (overtone C=O), 3072 (C-H aromatic), 2966 (C-H aliphatic), 1716 (C=O), 1400 (C=C), 1334 (C-N); ¹H NMR (CDCl₃): δ 1.25 (s, 9H, -C(CH₃)₃), 4.79 (s, 2H, 2H, CH₂-N), 7.31 (d, *J* = 8.4 Hz, 2H, benzene H₂, H₆), 7.36 (d, *J* = 8.4 Hz, 2H, benzene H₃, H₅), 7.66-7.69 (m, 2H, phthalimide H_{3'}, H_{4'}), 7.81 (dd, *J* = 3.1, 5.5 Hz, 2H, phthalimide H_{2'}, H_{5'}); MS: *m/z* (relative intensity): M⁺293 (16.31), 278 (100), 236 (28.04), 160 (46.68), 131 (34.90), 130 (11.93). Anal. Calcd. for C₁₉H₁₉NO₂ (293.36): C, 77.79; H, 6.23; N, 4.77. Found: C, 77.61; H, 6.75; N, 4.50. TLC (ethyl acetate/hexane [1:2]): R_f of phthalimide = 0.360, R_f of 4-*tert*-butyl benzyl bromide = 0.605 and R_f of compound **36** = 0.500.

4. 1-Phthalimidomethyl-3-methoxybenzene

To a solution of phthalimide (2 g, 13.6 mmol) in *N,N*-dimethylformamide (40 mL) was added 3-methoxybenzyl chloride (4 mL, 29.5 mmol) and potassium hydroxide solution (0.31 g, 5.5 mmol) 10 mL. The reaction mixture was refluxed for 6 hours at 190°C. The mixture was extracted with chloroform (30 mL) and water (3x15 mL). The organic phase was dried over anhydrous sodium sulfate, filtered and concentrated in vacuo. The residue was purified by column chromatography (silica gel 60 No. 1.07734) using hexane/ethyl acetate (4:1) as eluent. Recrystallization from chloroform/methanol gave compound **37** (0.50 g, 13.75 % yield) as a white solid crystal; mp 126-167°C. IR (KBr) (cm⁻¹): 3470 (overtone C=O), 3039 (aromatic C-H), 2953 (aliphatic C-H), 1709 (C=O), 1604, 1499 (C=C), 1393 (C-N); ¹H NMR (CDCl₃): δ 3.76 (s, 3H, OCH₃), 4.80 (s, 2H, CH₂-N), 6.78 (dd, *J* = 1.9, 8.2 Hz, 1H, benzene H₂), 6.95 (d, *J* = 2.4 Hz, 1H, benzene H₆), 6.99 (d, *J* = 7.5 Hz, 1H, benzene H₄), 7.21 (t, *J* = 8.4 Hz, 1H, benzene H₅), 7.66-7.72 (m, 2H, phthalimide H_{3'}, H_{4'}), 7.82 (dd, *J* = 3.0, 5.4 Hz, 2H, phthalimide H_{2'}, H_{5'}); MS: *m/z* (relative intensity): M⁺+H 268 (28.94), 267 (100), 234 (28.26), 206 (30.34), 180 (9.23), 130 (8.82), 77 (10.33). Anal. Calcd. for C₁₆H₁₃NO₃ (267.28): C, 71.80; H, 4.90; N, 5.24. Found: C, 71.78; H, 5.11; N, 4.89. TLC (ethyl acetate/hexane [1:2]): R_f of phthalimide = 0.294, R_f of 3-methoxybenzyl chloride = 0.695 and R_f of compound **37** = 0.412.

5. 1-Phthalimidomethyl-3-nitrobenzene

To a solution of phthalimide (2 g, 13.6 mmol) in *N,N*-dimethylformamide (40 mL) was added 3-nitrobenzyl chloride (5 g, 29.1 mmol) and potassium hydroxide solution (0.31 g, 5.5 mmol) 10 mL. The reaction mixture was refluxed for 8 hours at 190°C. The mixture was extracted with chloroform (30 mL) and water (3x15 mL). The organic phase was dried over anhydrous sodium sulfate, filtered and concentrated in vacuo. The residue was purified by column chromatography (silica gel 60 No. 1.07734) using hexane/ethyl acetate (4:1) as eluent. Recrystallization from chloroform/methanol gave compound **38** (1.31 g, 34.19 % yield) as a white needle crystal; mp 163-164°C. IR (KBr) (cm⁻¹): 3460 (overtone C=O), 3087 (aromatic C-H), 2933 (aliphatic C-H), 1719 (C=O), 1543 (C=C), 1350 (C-N); ¹H NMR (CDCl₃): δ 4.92 (s, 2H, CH₂-N), 7.49 (t, *J* = 7.8 Hz, 1H, benzene H5), 7.69-7.75 (m, 3H, benzene H6, phthalimide H3', H4'), 7.85 (dd, *J* = 3.0, 5.4 Hz, 2H, phthalimide H2', H5'), 8.11 (dd, *J* = 0.9, 7.8 Hz, 1H, benzene H4), 8.25 (s, 1H, benzene H2); MS: *m/z* (relative intensity): M⁺281 (10.52), 265 (100), 266 (22.83), 235 (67.78), 207 (9.17), 179 (5.01), 130 (5.82), 77 (8.28). Anal. Calcd. for C₁₅H₁₀N₂O₄·0.5H₂O (291.26): C, 61.86; H, 4.15; N, 9.62. Found: C, 62.03; H, 3.61; N, 9.10. TLC (ethyl acetate/hexane [4:1]): R_f of phthalimide = 0.601, R_f of 3-nitrobenzyl chloride = 0.637 and R_f of compound **38** = 0.562.

6. 1-Phthalimidomethyl-3-cyanobenzene

To a solution of phthalimide (1 g, 6.79 mmol) in N,N-dimethylformamide (40 mL) was added 3-(bromomethyl)benzonitrile (2.7 g, 13.8 mmol) and potassium hydroxide solution (0.16 g, 2.85 mmol) 10 mL. The reaction mixture was refluxed for 6 hours at 190°C. The mixture was extracted with chloroform (30 mL) and water (3x15 mL). The organic phase was dried over anhydrous sodium sulfate, filtered and concentrated in vacuo. The residue was purified by column chromatography (silica gel 60 No. 1.07734) using hexane/ethyl acetate (1:2) as eluent. Recrystallization from chloroform/methanol gave compound **39** (1.50 g, 44.70 % yield) as a white solid crystal; mp 148-149°C. IR (KBr) (cm⁻¹): 3466 (overtone C=O), 3072 (aromatic C-H), 2947 (aliphatic C-H), 2242 (C≡N), 1709 (C=O), 1492 (C=C), 1393 (C-N); ¹H NMR (CDCl₃): δ 4.84 (s, 2H, CH₂-N), 7.41 (t, *J* = 7.8 Hz, 1H, benzene H₅), 7.54 (d, *J* = 7.8 Hz, 1H, benzene H₆), 7.65 (d, *J* = 7.8 Hz, 1H, benzene H₄), 7.68 (s, 1H, benzene H₂), 7.71-7.75 (m, 2H, phthalimide H_{3'}, H_{4'}), 7.84 (dd, *J* = 3.0, 5.4 Hz, 2H, phthalimide H_{2'}, H_{5'}); MS: *m/z* (relative intensity): M⁺+H 263 (60.95), 262 (100), 244 (66.90), 233 (24.34), 205 (21.82), 130 (10.42), 105 (18.95), 77 (8.87). Anal. Calcd. for C₁₆H₁₀N₂O₂ (262.27): C, 73.27; H, 3.84; N, 10.68. Found: C, 73.69; H, 3.94; N, 10.59. TLC (ethyl acetate/hexane [4:1]): R_f of phthalimide = 0.576, R_f of 3-(bromomethyl) benzonitrile = 0.706 and R_f of compound **39** = 0.624.

CHAPTER IV

BIOLOGICAL EXPERIMENT

A. HIV-1 reverse transcriptase inhibitory activity test

Radioactivity test

1. Equipments and reagents

1. Analytical balance	Oterling
2. Centrifuge	Hettich Universal
3. Micropipette	Gilson
4. Shaking water bath	Clifton
5. β -Counter TRI-CARB 2100TR	Packard
6. Recombinant reverse transcriptase (RT)	Calbiochem
7. [methyl- ^3H]-Thymidine-5'-triphosphate (dTTP)	Amersham
8. Poly.(rA).oligo.(dT)	Amersham
9. Doxorubicin hydrochloride (adriamycin)	Sigma
10. DEAE-cellulose paper disc	Whatman
11. Dimethyl sulfoxide (DMSO)	Sigma
12. Scintillation fluid	Packard
13. Disodium hydrogenphosphate anhydrous	Merck
14. Absolute ethanol	J.T.Baker

2. Methods

2.1 Buffer and reagents preparation

- Preparation of 10 mL of the buffer mixture solution.

DW	7.57 mL
1 M Tris HCl pH 8.0	1.0 mL

2 M KCl	0.5 mL
1 M Mg(OAc) ₂	0.1 mL
2 M dithiothreitol (DDT)	0.03 mL
2.5% Nonnidet P-40	0.8 mL

2. Preparation of substrate solution per sample.

Buffer mixture solution	50.25 μ L
DW	12.0 μ L
[³ H] dTTP	0.25 μ L

3. Preparation of enzyme solution per sample.

Buffer mixture solution	10.0 μ L
BSA	2.0 μ L
Recombinant RT	0.1 μ L

2.2 Assay of RT (complete system)

The reaction mixture for the standard RT assay (final volume 100 μ L) contained the following:

Substrate solution	62.5 μ L
Poly(rA).oligo(dT)	10.0 μ L
DW	10.4 μ L
Sample solution	5.0 μ L
Enzyme solution	12.1 μ L

The synthesized compound was adjusted to 4 μ g/ μ L with DMSO. The enzyme solution was added immediately before incubation. The reaction mixture was incubated at 37°C for 60 minutes and then terminated by boiling at 100°C for 10 minutes. Eighty μ L of each assay mixture was applied at 2.3 cm circular Whatman DE81 cellular paper and dried for 1 hour. The membrane was washed batchwise with (4x7 mL) disodium hydrogenphosphate (Na₂HPO₄), followed by 2x7 mL of water and 2 mL of absolute ethanol. The membrane was dried and then transferred to a vial containing scintillation fluid (5 mL). The radioactivity was measured by a liquid scintillation counter.

2.3 Positive control of inhibitors.

The positive control of inhibitors was performed by using doxorubicin hydrochloride. The reaction mixture (final volume 100 μL) contained the following:

Substrate solution	62.5 μL
Poly(rA).oligo(dT)	10.0 μL
DW	10.4 μL
Doxorubicin hydrochloride (14.5 $\mu\text{g}/\mu\text{L}$)	5.0 μL
Enzyme solution	12.1 μL

The reaction mixture was incubated at 37°C for 60 minutes and followed the same procedure for the assay of RT.

2.4 Positive control of tested solution (complete system-sample).

The positive control assay consisted of DMSO instead of the synthetic compound. The reaction mixture (final volume 100 μL) contained the following:

Substrate solution	62.5 μL
DW	10.4 μL
DMSO	5.0 μL
Poly(rA).oligo(dT)	10.0 μL
Enzyme solution	12.1 μL

The reaction mixture was incubated at 37°C for 60 minutes and followed the same procedure for the assay of RT.

2.5 Negative control of teased solution (complete system-RT).

The negative control assay consisted of the same constituents as the assay of RT, but RT was omitted. The reaction mixture (final volume 100 μL) contained the following:

Substrate solution	62.5 μL
Poly(rA).oligo(dT)	10.0 μL
Buffer mixture solution	10.0 μL
BSA	2.0 μL
DMSO	5.0 μL

DW

10.5 μ L

The reaction mixture was incubated at 37°C for 60 minutes and followed the same procedure for the assay of RT.

2.6 Inhibition of RT activity.

The inhibition of RT incorporation of ^3H labeled substrates [^3H]dTTP into a polymer fraction by RT in the presence of the samples was calculated as followed:

$$(\%) \text{ IR} = \left[1 - \frac{[\text{cpm}(\text{complete system}) - \text{cpm}(\text{complete system-RT})]}{[\text{cpm}(\text{complete system-sample}) - \text{cpm}(\text{complete system-RT})]} \right] \times 100$$

where: (%) IR	= percent of relative inhibitory ratio
cpm	= count per minute
complete system	= reaction mixture which consisted of RT, template-primer, substrate, sample, and other reagents.
complete system-RT	= reaction mixture which consisted of template- primer, substrate and other reagents.
complete system-sample	= reaction mixture which consisted of RT, template-primer, substrate and other reagents.

All experiments were performed in triplicate. The average of the 2 closely values obtained from the experiment was used to calculate % IR.

B. In vitro cytotoxic activity testing

3- (4, 5-dimethylthiazol-2-yl)- 2, 5-diphenyltetrazolium bromide (MTT) assay

1. Equipments and reagents

1. Cell lines [human epidermoid carcinoma (KB), human cervical carcinoma (HeLa) and african green monkey kidney cell (vero)]
2. Growth medium, minimal essential medium (MEM) Gibco

3. PBS (phosphate buffered saline)	Gibco
4. Fetal bovine serum (FBS)	Gibco
5. 3- (4, 5-dimethylthiazol-2-yl)- 2, 5-diphenyltetrazolium bromide (MTT)	Sigma
6. Dimethyl sulfoxide (DMSO)	Sigma
7. 96-well disposable plate	Bio Basic
8. Incubator	Shel Lab
9. Micropipette	Biohit
10. Microplate reader	Bio Rad

2. Methods

2.1 Cell lines and culture conditions

Human epidermoid carcinoma (KB), human cervical carcinoma (HeLa), and african green monkey kidney cell (vero) were maintained in minimal essential medium (Gibco) 10% fetal bovine serum in a 95% air/5% CO₂ atmosphere at 37°C in a humidified incubator. Then the cells were subcultured and followed by trypsinization with 0.25% trypsin-EDTA solution.

2.2 MTT colorimetric assay

Cells at the density of 3,000 cells were seeded in 96 well plate containing 90 µL of growth medium per well. The well plate was incubated for 24 hours at 37°C with 5% CO₂ and 95% air atmosphere. Sample was diluted with DMSO and mix with 5% DMSO in phosphate-buffered saline (PBS). Ten µL of the sample solution was added in 96 well plate. The final concentration was 0.1-100 µg/mL. After incubating for 72 hours, 100 µL of MTT solution (0.5 mg/PBS 1 mL) was added and cells were incubated for 4 hours. One hundred µL of DMSO was added to each culture. Relative cell viability was obtained by scanning with an ELISA reader with a 550 nm filter.

2.3 Data Analysis

The experiments were performed in triplicate. The results were shown as plot between cell viability and concentration. The percentage of cell viability was calculated by following formula.

$$\% \text{ viability} = \frac{(\text{OD of sample at 550 nm})}{(\text{OD of control at 550 nm})} \times 100.$$

Where: % viability = percent of the cell survival
OD = optical density (absorbance) units

CHAPTER V

RESULTS AND DISCUSSION

A. General discussion

A key target in the search for effective drugs for AIDS therapy is the viral enzymes that have critical roles in the life cycle of the HIV-1, i.e., fusion, reverse transcriptase (RT) and protease (PR) enzyme (18-19). NNRTIs are attractive due to their low toxicity and high specificity. The absence of the binding to cellular polymerase of NNRTIs results in considerably lower cytotoxicity than nucleoside analogues. Recently, our research group has designed and synthesized a new class of non-nucleoside analogues in phthalimide series and tested for their HIV-1 RT inhibitory activities (Table 2). In order to investigate in more details in term of structural requirements for good inhibitory activity of compounds in this series, more derivatives were synthesized with modifying structures based on the previous comparative molecular field analysis (CoMFA) and comparative molecular similarity indices analysis (CoMSIA) studies (22) (Figure 13 and Figure 14).

The steric and electrostatic contour maps from CoMFA and CoMSIA models indicate that bulky substituents should be located at position C-3 and methyl group of pyrazine and the positive charge substituents are preferred at position C-6 of the pyrazine nucleus. This structural requirement is correspond to the CoMSIA hydrophobic contour maps (Figure 14 c) which illustrates the hydrophobic region around position C-3 and methyl group of the pyrazine ring (22). Based on the steric contour map from CoMFA and hydrophobic contour map from CoMSIA, more new compounds in phthalimide series, were synthesized and evaluated for their HIV-1 RT inhibitory. Since there are studies reported that some HIV-1 RT inhibitors, (e.g., AZT) also exhibited antitumor activity (12-14), the synthesized phthalimide derivatives were subjected to cytotoxic activity test as well.

Table 2. Structures of the previously synthesized phthalimide derivatives and HIV-1 RT inhibitory activities (22).

Cpd	R	% inhibition	Cpd	R	% inhibition
1		43	14		20
2		37	15		24
3		43	16		52

B. Synthesis of phthalimide derivatives

Based on the steric contour map from CoMFA and hydrophobic contour map from CoMSIA studies, more new compounds in phthalimide series, structures as shown in Figure 15 were synthesized.

Figure 15. Structures of the newly synthesized phthalimide compounds.

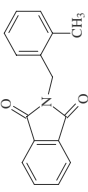

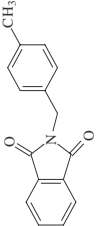

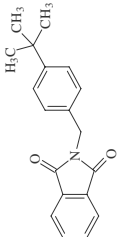

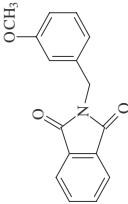

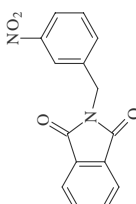

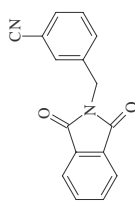

The phthalimide derivatives were synthesized by the reaction of phthalimide and substituted benzyl halide in the presence of potassium hydroxide, outline as shown in Figure 16. The synthesized compounds were purified by column chromatography and/or recrystallization and structures of pure compounds were identified by Fourier transform infrared spectroscopy (FT-IR), nuclear magnetic resonance (NMR) spectroscopy, mass spectrometry (MS), and elemental analysis.

Figure 16. Synthetic outline of phthalimide compounds.

The physical properties data and elemental analysis of the phthalimide compounds are given in Table 3. The products were obtained in between low and moderate percentage yields, approximately 14-45 %.

The IR spectrum of 1-phthalimidomethyl-4-*tert*-butylbenzene, compound **36** (Figure 17) shows the frequency of aromatic C-H stretching at 3072 cm^{-1} , aliphatic C-H stretching at 2966 cm^{-1} , C=O stretching at 1716 cm^{-1} , aromatic C=C stretching at 1550 and 1400 cm^{-1} and C-N stretching at 1334 cm^{-1} .

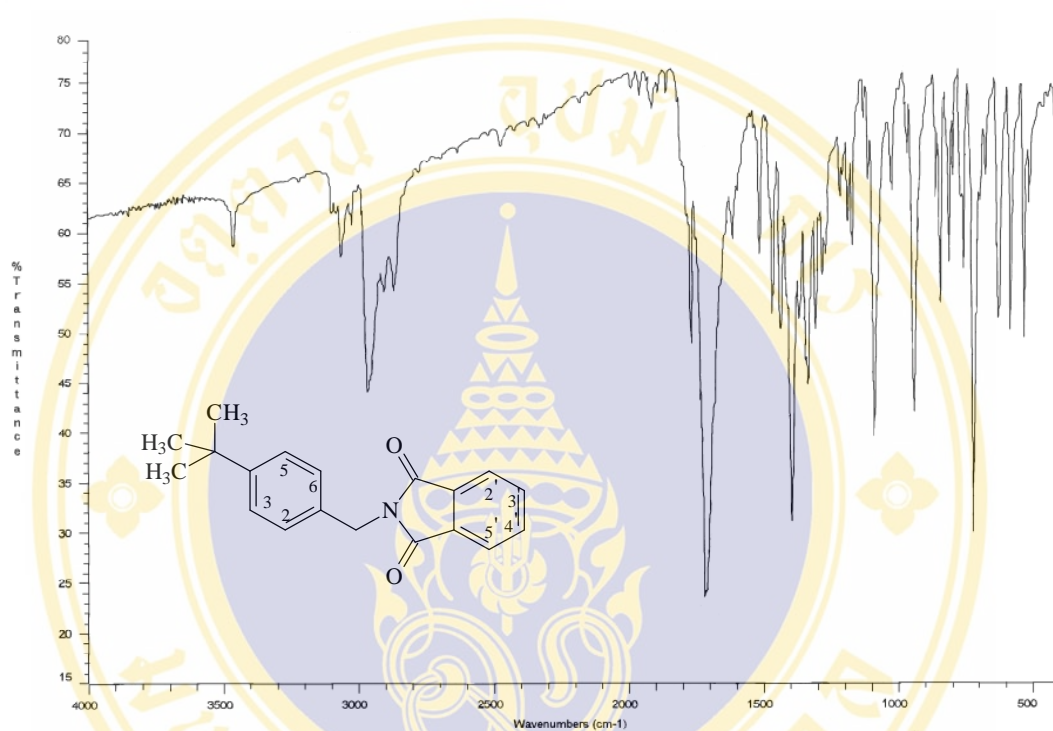

Figure 17. The IR spectrum of 1-phthalimidomethyl-4-*tert*-butylbenzene **36**

The ^1H NMR spectrum of compound **36** was shown in Figure 18. The singlet peak at 1.25 ppm represents the nine protons of *t*-butyl group. The singlet peak at 4.79 ppm represents the methylene protons between benzene and phthalimide rings. The doublet peaks at 7.31 ppm represent the two protons at position H2 and H6 of benzene which coupled to protons at position 3 and 5 (H3, H5) respectively ($J = 8.4\text{ Hz}$). The doublet peaks at 7.36 ppm represent the two protons at position H3 and H5 which coupled to protons at position 2 and 6 (H2, H6) respectively ($J = 8.4\text{ Hz}$). The multiplet peaks at 7.66-7.69 ppm show the two protons at positive H3' and H4' of the phthalimide nuclei. The doublet of doublet peaks at 7.81 ppm represent two protons at position H2' and H5' which coupled to protons at position 3' and 4' (H3', H4') respectively ($J = 5.5$ and 3.1 Hz).

The EI mass spectrum of compound **36** has characteristic peak at 236, 130, 104, 77 and 76 as shown in Figure 19. The proposed fragmentation mechanism is illustrated in Figure 20.

Figure 18. The ^1H NMR spectrum (300 MHz, CDCl_3) of 1-phthalimidomethyl-4-*tert*-butylbenzene **36**

Figure 19. The EI mass spectrum of 1-phthalimidomethyl-4-*tert*-butylbenzene **36**

Figure 20. Fragmentation patterns of 1-phthalimidomethyl-4-*tert*-butylbenzene **36**

The IR spectrum of 1-phthalimidomethyl-3-nitrobenzene, compound **38** (Figure 21) shows the frequency of aromatic C-H stretching at 3087 cm^{-1} , aliphatic C-H stretching at 2933 cm^{-1} , C=O stretching at 1719 cm^{-1} , aromatic C=C stretching at 1543 and 1450 cm^{-1} and C-N stretching at 1350 cm^{-1} .

Figure 21. The IR spectrum of 1-phthalimidomethyl-3-nitrobenzene **38**

The ^1H NMR spectrum of compound **38** is shown in Figure 22. The singlet peak at 4.92 ppm represents the methylene protons between benzene and phthalimide ring. The triplet peaks ($J = 7.8\text{ Hz}$) at 7.49 ppm represent proton at position H5 of benzene ring which coupled to protons at position 4 and 6 (H4, H6). The multiplet peaks at 7.69-7.75 ppm show the three protons at position H3' and H4' of the phthalimide and H6 of the benzene ring. The doublet of doublet peaks at 7.85 ppm represent two protons at position H2' and H5' of the phthalimide which coupled to H3' and H4' respectively ($J = 5.4$ and 3.0 Hz). The doublet of doublet peaks at 8.11 ppm represent proton at position H4 of benzene ring coupling to H5 ($J = 7.8\text{ Hz}$) and H6 ($J = 0.9\text{ Hz}$). The singlet peak at 8.25 ppm represents proton at position H2 of the benzene ring.

The EI mass spectrum of compound **38** has characteristic peak at 236, 130, 104, 77 and 76 as shown in Figure 23. The proposed fragmentation mechanism is illustrated in Figure 24

C. Evaluation of HIV-1 reverse transcriptase inhibitory activity

Radioactivity test

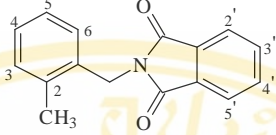

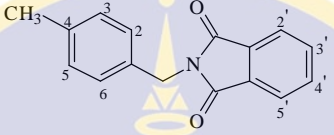

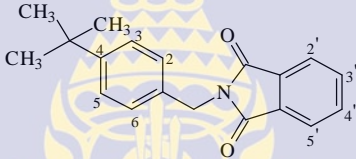

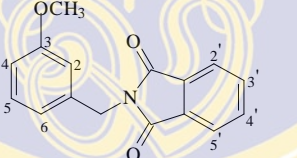

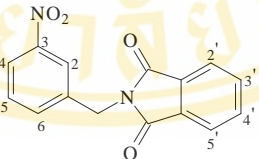

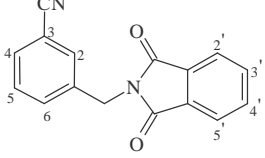

The 6 newly synthesized compounds were tested for HIV-1 RT activity with homopolymeric poly(rA).oligo(dT) as a template-primer and [³H]dTTP as substrate. The details of the principle and procedure of this assay were discussed in Chapter II and Chapter IV respectively. The reactions were performed under the condition described for the HIV-1 RT RNA dependent DNA polymerase activity assay (140). The results of this assay were reported as percentage of relative inhibitory activity ratio (%IR) which were determined based on count per minute of incorporated ³H labeled substrates into a polymer fraction by RT in the presence of the sample. The %IR was calculated as followed:

$$(\%) \text{ IR} = \left[1 - \frac{[\text{cpm}(\text{complete system}) - \text{cpm}(\text{complete system-RT})]}{[\text{cpm}(\text{complete system-sample}) - \text{cpm}(\text{complete system-RT})]} \right] \times 100$$

- where: (% IR) = percent of relative inhibitory ratio
 cpm = count per minute
 complete system = reaction mixture which consisted of RT, template-primer, substrate, sample, and other reagents.
 complete system-RT = reaction mixture which consisted of template-primer, substrate and other reagents.
 complete system-sample = reaction mixture which consisted of RT, template-primer, substrate and other reagents.

Doxorubicin hydrochloride (adriamycin) at 1.25 mM (678.8 µg/mL) was used as a positive control substance which exhibited 99.9% enzyme inhibition. The tested compounds were evaluated in triplicate at concentration 200 µg/mL. All of the tested compounds were dissolved in DMSO and were adjusted to the final concentration of DMSO of 5%. The result of activity testing was shown in Table 4.

Table 4. The inhibitory activity of the test compounds at concentration 200 $\mu\text{g/mL}$.

cpd	Structure	%IR
34	 (0.80 mM)	12.5
35	 (0.80 mM)	12.4
36	 (0.68 mM)	22.9
37	 (0.75 mM)	18.9
38	 (0.71 mM)	14.6
39	 (0.76 mM)	7.9

Note: Doxorubicin hydrochloride at concentration 678.8 $\mu\text{g/mL}$ (1.25 mM) exhibited 99.9% IR

Compounds in this series showed low inhibitory activity between 7.9-22.9 %IR. However, the concentrations of the tested compounds used in this assay was between 0.68-0.80 mM which were still lower of the positive control, doxorubicin, 1.25 mM

It should be mentioned that if different template-primer is used in the experiment, it might end up with different %IR (146-147). NNRTIs usually bind to the allosteric binding site which is clearly distinct from the substrate-binding site of enzyme, indicating that the binding of the enzyme with substrate is not influenced by the inhibitor. NNRTIs are noncompetitive with respect to the template-primer. However, mechanism of inhibition, i.e., competitive or noncompetitive is also depending on the template-primer, substrate, and divalent cation used in the assay (146). The unsatisfactory inhibitory activity of the synthesized derivatives might due to unappropriated assay condition. The more efficient template-primer as well as other optimal experimental conditions should be found out for the further study. Moreover, the low activity of these derivatives may resulted from the shape and size of the substituent of the benzene ring. The considered bulky group at meta or para position (designed from CoMFA and CoMSIA studies) does not provide appropriate steric effect for better activity. Bulkier substituent(s) should be tried to put at meta or para or both positions to improve the activity. The contour map of electrostatic field should be considered as well for modifying structures to obtain more potent derivatives.

D. Evaluation of cytotoxic activity

The cytotoxicity was determined by using MTT colorimetric assay. The three cell lines, human epidermoid carcinoma (KB), human cervical carcinoma (HeLa), and african green monkey kidney cell (vero) were used in the assay. The previously and newly synthesized derivatives were evaluated for cytotoxic activity. The details of the principle and procedure of this assay were discussed in Chapter II and Chapter IV respectively. The results were shown as the percentage of cell viability calculated by following equation.

$$\% \text{ viability} = \frac{(\text{OD of sample at 550 nm})}{(\text{OD of control at 550 nm})} \times 100$$

Where: % viability = percent of the cell survival

OD = optical density (absorbance) units

The tested compounds were evaluated in triplicate at concentration 0.1-100 $\mu\text{g/mL}$. All of the tested compounds were dissolved in DMSO and were adjusted to the final concentration of DMSO of 5%. As shown in Table 5 most of the compounds showed similar cytotoxic activity with IC_{50} values over 100 $\mu\text{g/mL}$, except for compound **36**. The IC_{50} values of compound **36** for KB and HeLa cell lines were 50 and 62 $\mu\text{g/mL}$ (0.17 and 0.21 μM) respectively and higher than 100 $\mu\text{g/mL}$ for vero cell line. Therefore, there was no correlation between HIV-1 RT and cytotoxic activity found in this phthalimide series.

CHAPTER VI

CONCLUSION

Six new derivatives in the phthalimide series have been designed and synthesized (based on the previous 3D QSAR, CoMFA and CoMSIA studies). These derivatives were synthesized using phthalimide and substituted benzyl halide in the presence of potassium hydroxide. The RT inhibitory activity assay were determined by radiometric method, using 200 µg/mL of the inhibitors. The assay was performed using poly(rA).oligo(dT) as template-primer, [³H]dTTP as substrate, and doxorubicin (adriamycin) 1.25 mM as a positive control. The synthesized compounds showed low inhibitory activity in the range of 7.9-22.9 % inhibition. The unsatisfactory activity of these derivatives may be due to the inappropriated assay conditions or the bulkiness of the substituent at meta or para position of the benzene ring still not adequate for better activity.

The previously and newly synthesized phthalimide derivatives have been subjected to cytotoxic activity testing using MTT colorimetric method against the cancer cell lines KB and HeLa and normal vero cell line. Only 1-phthalimidomethyl-4-*tert*-butylbenzene, compound **36** showed promising cytotoxic activity with less toxic to normal cell.

The ¹H NMR spectrum (300 MHz, CDCl₃) of 1-phthalimidomethyl-3-cyanobenzene

BIOGRAPHY

NAME	Ms. Suratsawadee Piyaviriyakul
DATE OF BIRTH	18 November 1973
PLACE OF BIRTH	Krabee, Thailand
INSTITUTION ATTENDED	Ramkhamhaeng University, Bachelor of Science in Science Mahidol University, : Master of Science in Pharmaceutical Chemistry and Phytochemistry
RESEARCH GRANT	Supported in part by the Thesis Grant, Faculty of Graduate Studies, Mahidol University
